

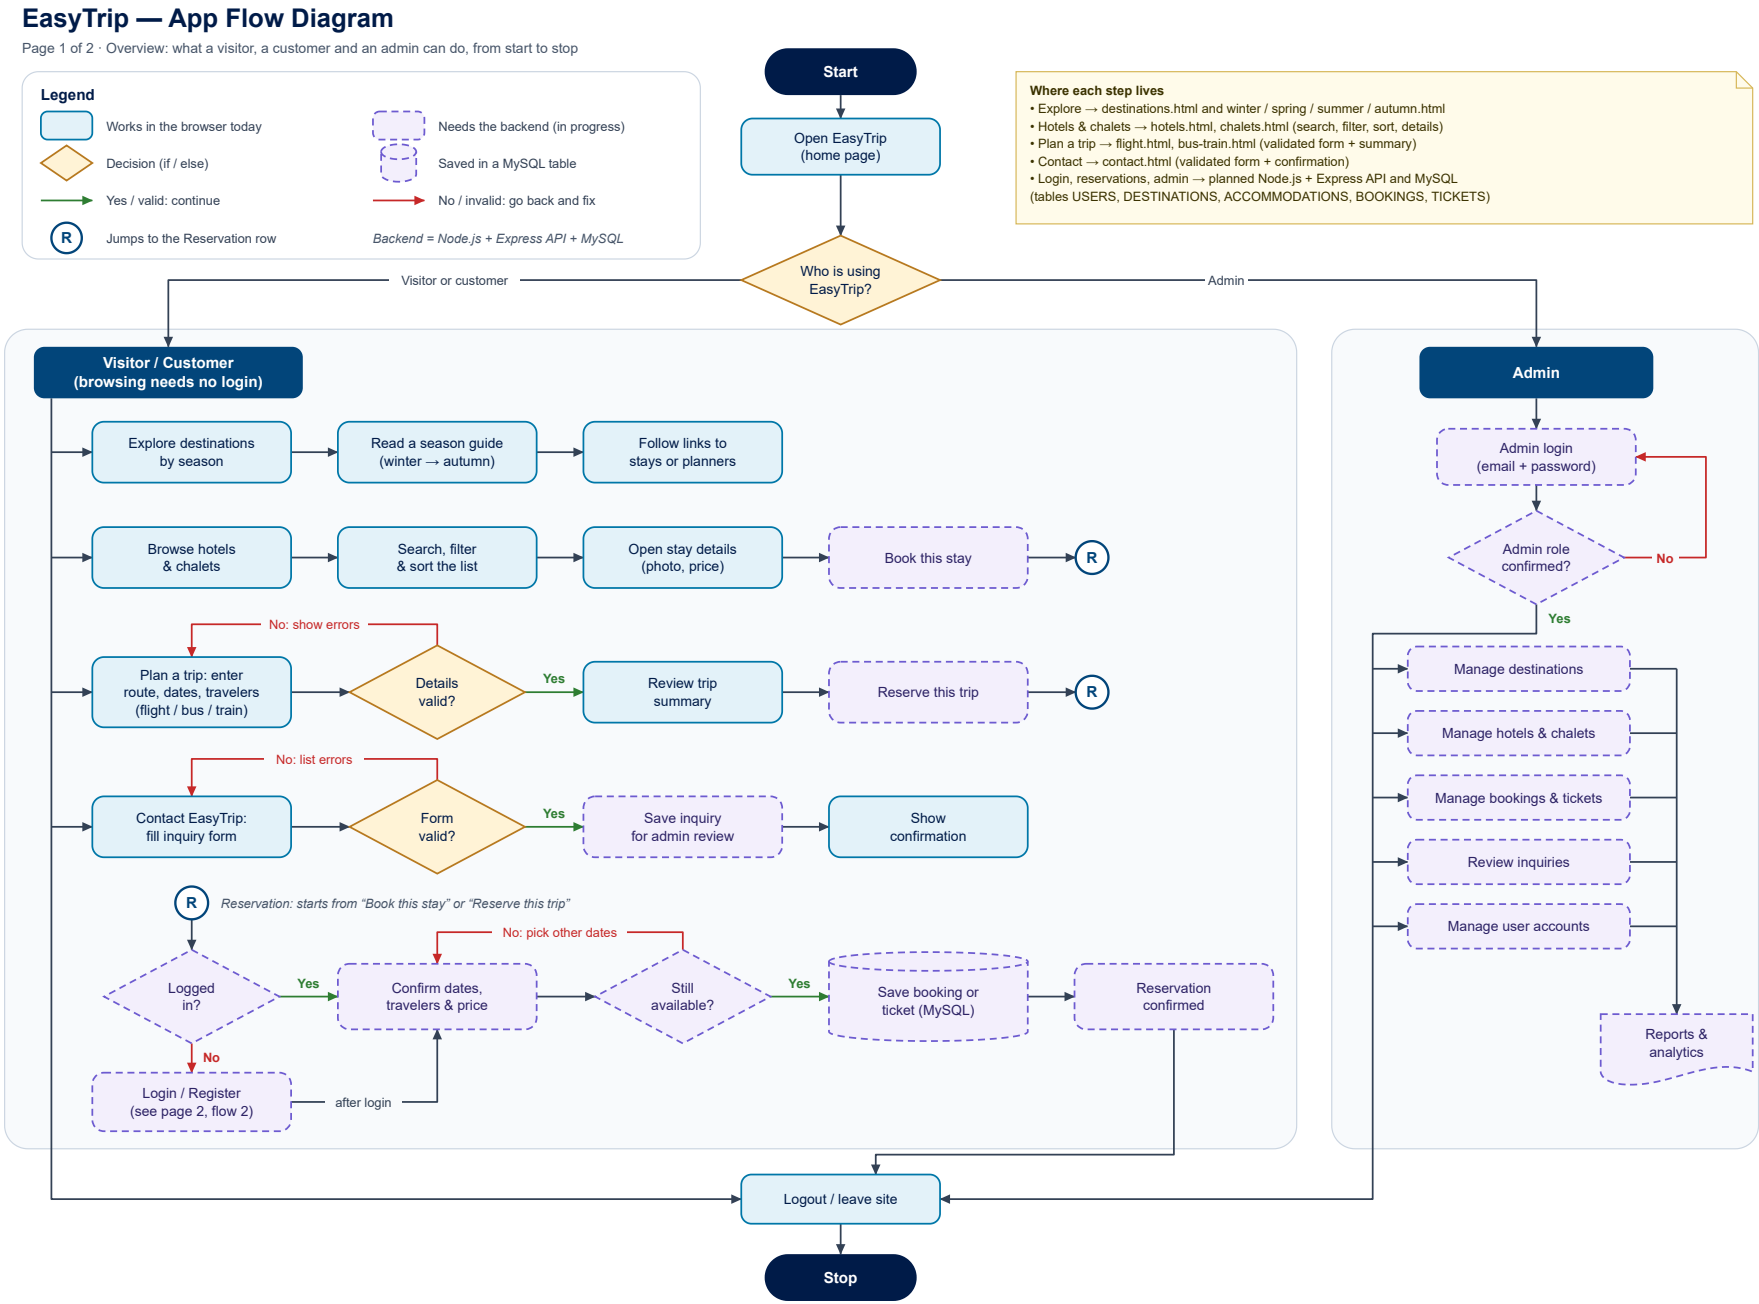

Figure 1 · Overview. Every path from Start to Stop for a visitor or customer and for an admin. The R circles link “Book this stay” and “Reserve this trip” to the reservation row.

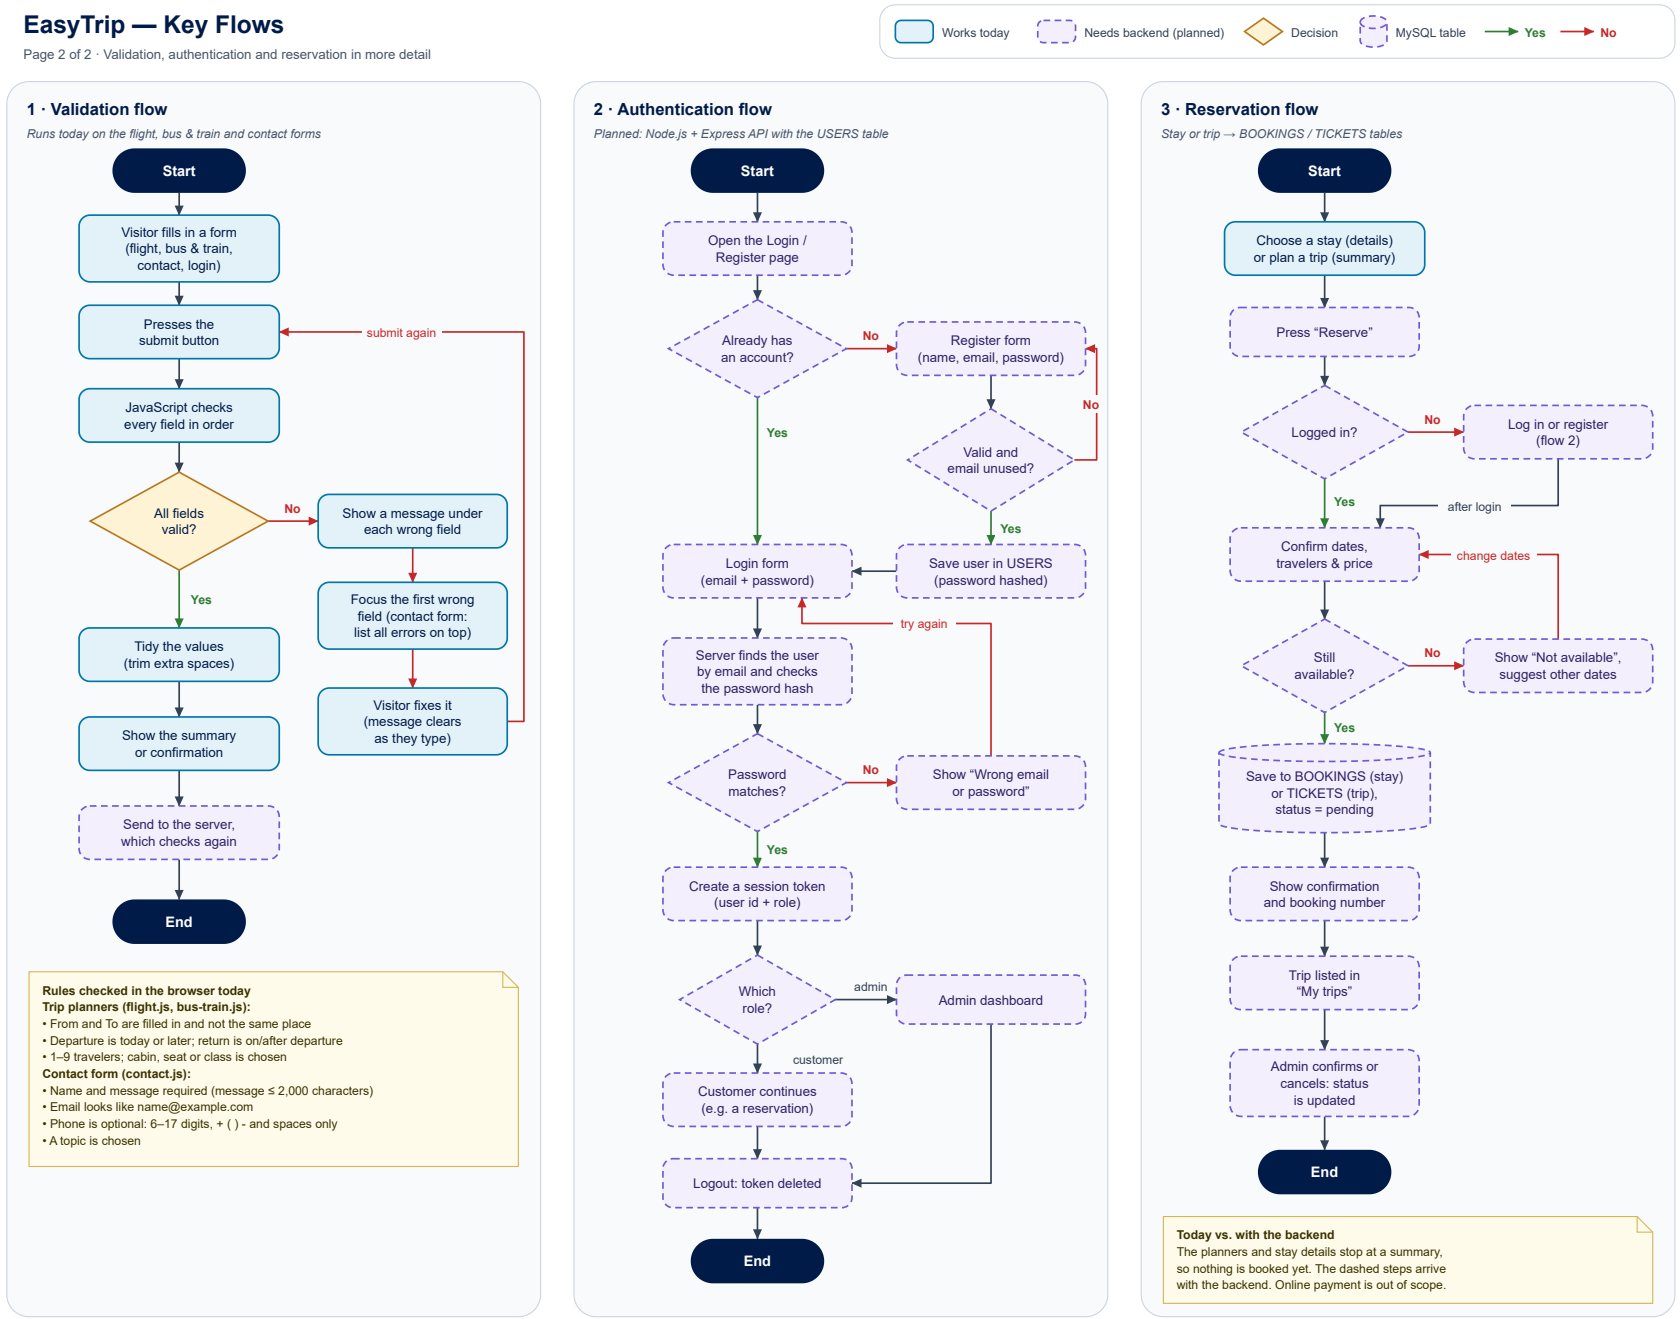

Figure 2 · Key flows. Validation, authentication and reservation in more detail, with the rules the forms check today.

EasyTrip — App Flow: Explanation

Web Programming I · Team: Sleiman Ghattas, Achraf Nazha

Overview

Every visit starts on the home page, then splits by role. A visitor or customer can browse the whole site without logging in; an admin must log in first. Both paths end at *Logout / leave site*, then Stop.

Browse and explore

Visitors explore destinations by season (`destinations.html` and the four season pages), or browse hotels and chalets (`hotels.html`, `chalets.html`): they search, filter by price or setting, sort, and open a details dialog. This is the discovery part of the app and needs no account.

1 · Validation flow

Used by every form: the flight and bus & train planners, the contact form and, later, login and register. When the visitor submits, JavaScript checks each field in order. **If all fields are valid**, the values are tidied and a summary or confirmation is shown. **Otherwise** each wrong field gets its own message, focus moves to the first one, and the visitor fixes it and submits again.

Examples of the rules: From and To must be different, the departure date can't be in the past, the return can't be before the departure, there must be 1–9 travelers, and the email must look like `name@example.com`. With the backend, the server checks the data again before saving it.

2 · Authentication flow

A new user registers with a name, email and password. **If the input is valid and the email is unused**, the account is saved in the `USERS` table with a hashed password; otherwise an error is shown. To log in, the server finds the user by email and compares the password hash. **If it matches**, a session token holding the user id and role is created; **otherwise** “Wrong email or password” is shown and the user tries again. The role decides where the user goes: customers continue (for example to a reservation), admins go to the dashboard. Logging out deletes the token.

3 · Reservation flow

The customer chooses a stay (from its details) or plans a trip (from the validated summary) and presses Reserve. **If they are not logged in**, they go through the authentication flow first. They confirm the dates, travelers and price; **if the stay or trip is still available**, it is saved in `BOOKINGS` (stays) or `TICKETS` (transport) with the status *pending*. The customer sees a confirmation and the trip appears in “My trips”. An admin later confirms or cancels it, which updates the status.

Contact and admin

The contact form uses the same validation flow; today it then shows a confirmation, and with the backend the inquiry is also saved for an admin to review. After logging in with the admin role, the admin manages destinations, hotels and chalets, bookings and tickets, inquiries and user accounts. These actions feed the reports and analytics.

How it fits together

Discovery leads visitors to the planners. The validation flow makes sure every form sends clean data. The authentication flow controls who can reserve and who can manage content. The reservation flow turns a validated plan or a chosen stay into a saved booking that both the customer and the admin can see. Today the frontend covers browsing, validation and summaries; login, saved reservations and the admin area arrive with the Node.js / MySQL backend described in the project proposal.
